Use Of Artificial Intelligence

In developing the BONTEN project, we used AI mainly as a learning and support tool. As a group, we followed the Yellow-Light strategy from the project guide, meaning AI helped us understand concepts and debug issues, but the actual work and decisions remained ours. Throughout the process, AI became something we used to think more clearly, fix mistakes faster, and improve the quality of our work without replacing our own effort.

We used AI frequently when we needed help understanding backend or frontend concepts that were slowing us down. Sometimes our JavaScript functions were acting unexpectedly, or our CSS layout kept breaking, and we didn't fully understand why. AI helped explain these issues in a clearer way, allowing us to continue coding with more confidence. It didn't solve things for us, but it helped us see what we were doing wrong so we could correct it ourselves.

AI also played a role in debugging errors across different parts of the system. When our logs showed confusing messages or an Express route failed, we used AI to interpret the errors and guide us toward the right area of the code to fix. We also relied on it when our payment flow was not working at the start. AI helped us understand the logic issues that were causing the failure, and from there we rewrote and tested the fixes on our own.

Another area where AI supported us was styling and layout troubleshooting. When the UI shifted or certain elements refused to align properly, we asked AI for advice on what might be causing the conflict in our CSS. This helped us find the problem faster, but we still did the actual corrections manually by rewriting the structure according to our design.

We also used AI explicitly in the `populate_events.sql` file, mostly to guide us on bulk inserts and how to structure test data properly. We reviewed all suggestions and then wrote the final SQL file ourselves to make sure everything matched our database structure.

Outside of coding, AI helped us in a different way: we used tools like Grammarly and similar AI editors to refine our documentation and write-ups. This improved the clarity, grammar, and flow of our reports without changing the meaning of what we wrote. It allowed us to present our work more professionally while still keeping our own ideas and voice.

Overall, our use of AI was supportive, educational, and reflective. It helped us learn faster, solve issues more confidently, and communicate our work more clearly. We made sure to understand every suggestion before applying it, and we always did the final implementation ourselves. By using AI responsibly, we strengthened both our project and our own skills as developers.

We want to highlight Claude AI, ChatGPT and Antigravity as the AI tools used in aid for coding.
